Politecnico di Torino
skenz.it/os stefano.scanzio@polito.it

File System

- The file system is one of the most visible aspects of an OS
- It provides mechanisms to save data (permanently)
- It includes management of
 - > Files
 - Direttories
 - Disks and disk partitions

- Information is store for a long period of time
 - independently from
 - Termination of programs/processes, power supply, etc.
- From the logical point of view a file is
 - > A set of correlated information
 - All information (i.e., numbers, characters, images, etc.) are stored in a (electronic) device using a coding system
 - Contiguous address space

How is this information encoded?

What is the actual organization of this space?

ASCII encoding

De-facto standard

ASCII, American Standard
 Code for Information Interchange

- Originally based on the English alphabet
- 128 characters are coded in 7-bit (binary numbers)
- > Extended ASCII (or high ASCII)
 - Extension of ASCII to 8-bit and 255 characters
 - Several versions exist

• ISO 8859-1 (ISO Latin-1), ISO 8859-2 (Eastern European languages), ISO 8859-5 for Cyrillic languages, etc.

The alphabet of Klingom language is not supported by Extended ASCII

128 total characters 32 not printable 96 printable

Extended ASCII table

Unicode encoding

- Industrial standard that includes the alphabets for any existing writing system
 - > It contains more 110,000 characters
 - > It includes more than 100 sets of symbols
- Several implementations exist
 - UCS (Universal Character Set)
 - UTF (Unicode Tranformation Format)
 - UTF-8, groups of 8 bits size (1, 2, 3 or 4 groups)
 - ASCII coded in the first 8 bits
 - UTF-16, groups of 16 bits size (1 or 2 groups)
 - UTF-32, groups of 32 bits size (fixed length)

Textual and binary files

- A file is basically a sequence of bytes written one after the other
 - > Each byte includes 8 bits, with possible values 0 or 1
 - > As a consequence all files are binary
- Normally we can distinguish between
 - > Textual files (or ASCII)
 - Binary files

Executables, Word, Excel, etc.

C sources, C++, Java, Perl, etc.

Remark: UNIX/Linux k

The UNIX/Linux kernel does not distinguish between binary and textual files

Textual files (or ASCII)

- Files consisting of data encoded in ASCII
 - Sequence of 0 and 1, which (in groups of 8 bit) codify ASCII symbols
- Textual files are usually "line-oriented"
 - Newline: go to the next line
 - UNIX/Linux and Mac OSX
 - Newline = 1 character
 - Line Feed (go to next line, LF, 10₁₀)
 - Windows
 - Newline = 2 characters
 - Line Feed (go to next line, LF, 10₁₀)
 - + Carriage Return (go to beginning of the line, CR, 13₁₀)

Binary Files

- A sequence of 0 and 1, not "byte-oriented"
- The smallest unit that can be read/write is the bit
 - Non easy the management of the single bit
 - ➤ They usually include every possible sequence of 8 bits, which do not necessarily correspond to printable characters, new-line, etc.
- Why are binary files used?
 - Compactness
 - Examples
 - Number 100000₁₀
 - Text/ASCII format: 6 characters, i.e., 6 bytes
 - Binary format: coded as integer (short) on 4 bytes

Example

```
String
"ciao"
                                                  Textual or binary file
'c' 'i' 'a' 'o'
99_{10} 105_{10} 97_{10} 111_{10}
01100011, 01101001, 01100100, 01101111,
"231"
                                                    Integer number
12' 13' 11'
                                                       Textual file
50<sub>10</sub> 51<sub>10</sub> 49<sub>10</sub>
00110010, 00110011, 00110001,
"231"
                               Integer number
                                  Binary file
"231<sub>10</sub>"
11100111<sub>2</sub>
```

Serialization

- Process of translating a structure (e.g., C struct) into a storable format
 - Using serialization, a struct can be stored or transmitted (on the network) as a single entity
 - When the sequence of bits is read, it is done in accordance with the serialization process, and the struct is reconstructed in an identical manner
- Many languages support serialization using R/W operations on a file

Example

```
struct mys {
  int id;
  long int rn;
  char n[L], c[L];
  int mark;
} s;
```

Binary:
Serialization
Ctr on 8 bits (ASCII)

Binary:
Serialization
Ctr on 16 bits (UNICODE)
N.B. File dimension

Text:
Single fields
Characters on 8 bits (ASCII)

1 100000 Romano Antonio 25

† Romano ÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÀÀ Antonio ÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌÌ

ISO C Standard Library

- I/O operations with ANSI C can be performed through different categories of functions
 - Character by character
 - Row by row
 - > Formatted I/O
 - Binary I/O
 - > Read examples
 - https://www.skenz.it/cs/c language/file reading 1
 - Write examples
 - https://www.skenz.it/cs/c language/file writing 1
 - Binary I/O examples
 - https://www.skenz.it/cs/c language/write and read a binary file

ISO C Standard Library

- Standard I/O is "fully buffered"
 - ➤ The I/O operation is performed only when the I/O buffer is full
 - ➤ The "flush" operation indicates the actual write of the buffer to the I/O

```
#include <stdio.h>
void setbuf (FILE *fp, char *buf);
int fflush (FILE *fp);
```

Standard error is never buffered

For concurrent processes, use: setbuf (stdout, 0); fflush (stdout);

Open and close a file

```
#include <stdio.h>
FILE *fopen (char *path, char *type);
FILE *fclose (FILE *fp);
```

Access methods

- > r, rb, w, wb, a, ab r+, r+b, etc.
- ➤ The UNIX kernel does not make any difference between textual files (ASCII) and binary files
 - The "b" option has no effect, e.g. "r"=="rb", "w"=="wb", etc.

I/O character by character

```
#include <stdio.h>
int getc (FILE *fp);
int fgetc (FILE *fp);
int putc (int c, FILE *fp);
int fputc (int c, FILE *fp);
```

Returned values

- > A character on success
- EOF on error, or when the end of the file is reached

The function

- getchar is equivalent to getc (stdin)
- putchar is equivalent to putc (c, stdout)

I/O row by row

```
#include <stdio.h>
char gets (char *buf);
char *fgets (char *buf, int n, FILE *fp);
int puts (char *buf);
int *fputs (char *buf, FILE *fp);
```

Returned values

- buf (gets/fgets), or a non-negative value in the case of success (puts/fputs)
- NULL (gets/fgets), or EOF for errors or when the end of file is reached (puts/fputs)
- Lines must be delimited by "new-line"

Formatted I/O

```
#include <stdio.h>
int scanf (char format, ...);
int fscanf (FILE *fp, char format, ...);
int printf (char format, ...);
int fprintf (FILE *fp, char format, ...);
```

- High flexibility in data manipulation
 - > Formats (characters, integers, reals, etc.)
 - Conversions

Binary I/O

```
#include <stdio.h>
size_t fread (void *ptr, size_t size,
    size_t nObj, FILE *fp);
size_t fwrite (void *ptr, size_t size,
    size_t nObj, FILE *fp);
```

- Each I/O operation (single) operates on an aggregate object of specific size
 - With getc/putc it would be necessary to iterate on all the fields of the struct
 - With gets/puts it is not possible, because both would terminate on NULL bytes or new-lines

Binary I/O

between the two cases

```
#include <stdio.h>
size_t fread (void *ptr, size_t size,
    size_t nObj, FILE *fp);
size_t fwrite (void *ptr, size_t size,
    size_t nObj, FILE *fp);
```

Returned values

- Number of objects written/read
- For any large parameter nObj

 If the returned value does not correspond to the ferror and feof can be used to distinguish
 - An error has occurred
 - The end of file has been reached

Binary I/O

```
#include <stdio.h>
size_t fread (void *ptr, size_t size,
    size_t nObj, FILE *fp);
size_t fwrite (void *ptr, size_t size,
    size_t nObj, FILE *fp);
```

- Often used to manage binary files
 - serialized R/W (single operation for the whole struct)
 - Potential problems in managing different architectures
 - Data format compatibility (e.g., integers, reals, etc.)
 - Different offsets for the fields of the struct

POSIX Standard Library

- I/O in UNIX can be entirely performed with only functions
 - > open, read, write, Iseek, close
- This type of access
 - ➤ Is part of POSIX and of the Single UNIX Specification, but not of ISO C
 - ➤ It is normally defined with the term "unbuffered I/O", in the sense that each read or write operation corresponds to a system call

- In the UNIX kernel a "file descriptor" is a nonnegative integer
- Conventionally (also for shells)
 - > Standard input
 - 0 = STDIN FILENO
 - > Standard output
 - 1 = STDOUT_FILENO
 - > Standard error
 - 2 = STDERR_FILENO

These descriptors are defined in the headers file **unistd.h**

```
#include <sys/types.h>
#include <sys/stat.h>
#include <fcntl.h>

int open (const char *path, int flags);

int open (const char *path, int flags,
    mode_t mode);
```

- It opens a file defining the permissions
- Returned values
 - > The descriptor of the file on success
 - > -1 on error

int flags,

mode t mode

const char *path,

int open

);

- It can have 2 or 3 parameters
 - > The **mode** parameter is optional
- Path indicates the file to open
- Flags has multiple options
 - Can be obtained with the OR bit-by-bit of constants defined in the header file fcntl.h
 - One of the following three constants is mandatory
 - O_RDONLY open for read-only access
 - O_WRONLY open for write-only access
 - O_RDWR open for read-write access

```
int open (
   const char *path,
   int flags,
   mode_t mode
);
```

Optional constants

O CREAT creates the files if not exist

O_EXCL error if O_CREAT is set and the file

exists

O TRUNC remove the content of the file

O_APPEND append to the file

O_SYNC
 each write waits that the physical

write operation is finished

before continuing

• ...

- Mode specifies access permissions
 - > S_I[RWX]USR rwx --- ---
 - ➤ S_I[RWX]GRP --- rwx ---
 - > S_I[RWX]OTH --- rwx

```
int open (
  const char *path,
  int flags,
  mode_t mode
);
```

When a file is created, actual permissions are obtained from the **umask** of the user owner of the **process**

System call read()

```
#include <unistd.h>
int read (int fd, void *buf, size_t nbytes);
```

- Read from file fd a number of bytes equal to nbytes, storing them in buf
- Returned values
 - number of read bytes on success
 - > -1 on error
 - > 0 in the case of EOF

System call read()

```
#include <unistd.h>
int read (int fd, void *buf, size_t nbytes);
```

- The returned value is lower that nbytes
 - ➤ If the end of the file is reached before **nbytes** bytes have been read
 - If the pipe you are reading from does not contain nbytes bytes

System call write()

```
#include <unistd.h>
int write (int fd, void *buf, size_t nbytes);
```

- Write nbytes bytes from buf in the file identified by descriptor fd
- Returned values
 - ➤ The number of written bytes in the case of success, i.e., normally **nbytes**
 - > -1 on error

System call write()

```
#include <unistd.h>
int write (int fd, void *buf, size_t nbytes);
```

Remark

- > write writes on the system buffer, not on the disk
 - fd = open (file, O_WRONLY | O_SYNC);
- O_SYNC forces the sync of the buffers, but only for ext2 file systems

Examples: File R/W

```
float data[10];
if ( write(fd, data, 10*sizeof(float)) == (-1) ) {
   fprintf (stderr, "Error: Write %d).\n", n);
}
}
```

writing of the vector data (of float)

```
struct {
  char name[L];
  int n;
  float avg;
} item;
if ( write(fd,&item,sizeof(item))) == (-1) ) {
  fprintf (stderr, "Error: Write %d).\n", n);
  }
}
```

Writing of the serialized struct item (with 3 fields)

System call Iseek()

```
#include <unistd.h>
off_t lseek (int fd, off_t offset, int whence);
```

- The current position of the file offset is associated to each file
 - ➤ The system call Iseek assigns the value **offset** to the file offset

System call Iseek()

```
#include <unistd.h>
off_t lseek (int fd, off_t offset, int whence);
```

- whence specifies the interpretation of offset
 - If whence==SEEK_SET
 - The offset is evaluated from the beginning of the file
 - If whence==SEEK_CUR
 - The offset is evaluated from the current position
 - If whence==SEEK_END
 - The offset is evaluated from the end of the file

The value of **offset** can be positive or negative

It is possible to leave "holes" in a file (filled with zeros)

System call Iseek()

```
#include <unistd.h>
off_t lseek (int fd, off_t offset, int whence);
```

- Returned values
 - > new offset on success
 - > -1 on error

System call close()

```
#include <unistd.h>
int close (int fd);
```

- Returned values
 - > 0 on success
 - > -1 on error
- All the open files are closed automatically when the process terminates

Example: File R/W

```
#include <sys/stat.h>
#include <fcntl.h>
#include <unistd.h>
#define BUFFSIZE 4096
int main(void) {
  int nR, nW, fdR, fdW;
 char buf[BUFFSIZE];
  fdR = open (argv[1], O RDONLY);
  fdW = open (argv[2], O WRONLY | O CREAT | O TRUNC,
                       S IRUSR | S IWUSR);
  if (fdR==(-1) || fdW==(-1) ) {
    fprintf (stdout, "Error Opening a File.\n");
    exit (1);
```

Example: File R/W

```
while ( (nR = read (fdR, buf, BUFFSIZE)) > 0 ) {
    nW = write (fdW, buf, nR);
    if (nR!=nW)
      fprintf (stderr,
        "Error: Read %d, Write %d).\n", nR, nW);
  if (nR < 0)
    fprintf (stderr, "Write Error.\n");
  close (fdR);
  close (fdW);
                                     Error check on the last
  exit(0);
                                       reading operation
```

This program works indifferently on text and binary files
